Tikhonov and Ivanov Regularization

Hypothesis Spaces

- We've spoken vaguely about "bigger" and "smaller" hypothesis spaces
- In practice, convenient to work with a **nested sequence** of spaces:

$$\mathcal{F}_1 \subset \mathcal{F}_2 \subset \mathcal{F}_n \cdots \subset \mathcal{F}$$

Decision Trees

- $\mathcal{F} = \{\text{all decision trees}\}$
- $\mathcal{F}_n = \{\text{all decision trees of depth } \leq n\}$

Complexity Measures for Decision Functions

- Number of variables / features
- Depth of a decision tree
- Degree of polynomial
- A measure of smoothness:

$$f \mapsto \int \left\{ f''(t) \right\}^2 dt$$

- How about for linear models?
 - ullet ℓ_0 complexity: number of non-zero coefficients
 - ℓ_1 "lasso" complexity: $\sum_{i=1}^{d} |w_i|$, for coefficients w_1, \ldots, w_d
 - ℓ_2 "ridge" complexity: $\sum_{i=1}^d w_i^2$ for coefficients w_1, \ldots, w_d

Nested Hypothesis Spaces from Complexity Measure

- ullet Hypothesis space: ${\mathcal F}$
- Complexity measure $\Omega: \mathcal{F} \to \mathbb{R}^{\geqslant 0}$
- Consider all functions in F with complexity at most r:

$$\mathcal{F}_r = \{ f \in \mathcal{F} \mid \Omega(f) \leqslant r \}$$

- If Ω is a norm on \mathcal{F} , this is a **ball of radius** r in \mathcal{F} .
- Increasing complexities: $r = 0, 1.2, 2.6, 5.4, \dots$ gives nested spaces:

$$\mathcal{F}_0 \subset \mathcal{F}_{1.2} \subset \mathcal{F}_{2.6} \subset \mathcal{F}_{5.4} \subset \cdots \subset \mathcal{F}$$

Constrained Empirical Risk Minimization

Constrained ERM (Ivanov regularization)

For complexity measure $\Omega: \mathcal{F} \to \mathbb{R}^{\geqslant 0}$ and fixed $r \geqslant 0$,

$$\min_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} \ell(f(x_i), y_i)$$
s.t. $\Omega(f) \leq r$

- Choose r using validation data or cross-validation.
- Each r corresponds to a different hypothesis spaces. Could also write:

$$\min_{f \in \mathcal{F}_r} \frac{1}{n} \sum_{i=1}^n \ell(f(x_i), y_i)$$

Penalized Empirical Risk Minimization

Penalized ERM (Tikhonov regularization)

For complexity measure $\Omega: \mathcal{F} \to \mathbf{R}^{\geqslant 0}$ and fixed $\lambda \geqslant 0$,

$$\min_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^{n} \ell(f(x_i), y_i) + \lambda \Omega(f)$$

- Choose λ using validation data or cross-validation.
- (Ridge regression formulation in Homework #1 was of this form.)

Ivanov vs Tikhonov Regularization

- Let $L: \mathcal{F} \to \mathbf{R}$ be any performance measure of f
 - e.g. L(f) could be the empirical risk of f
- For many L and Ω , Ivanov and Tikhonov are "equivalent".
- What does this mean?
 - Any solution you could get from Ivanov, can also get from Tikhonov.
 - Any solution you could get from Tikhonov, can also get from Ivanov.
- In practice, both approaches are effective.
- Tikhonov convenient because it's unconstrained minimization.

Proof of equivalence based on Lagrangian duality - a topic of Lecture 3.

Ivanov vs Tikhonov Regularization (Details)

Ivanov and Tikhonov regularization are equivalent if:

• For any choice of r > 0, the Ivanov solution

$$f_r^* = \mathop{\arg\min}_{f \in \mathcal{F}} L(f) \text{ s.t. } \Omega(f) \leqslant r$$

is also a Tikhonov solution for some $\lambda > 0$. That is, $\exists \lambda > 0$ such that

$$f_r^* = \underset{f \in \mathcal{F}}{\operatorname{arg\,min}} L(f) + \lambda \Omega(f).$$

② Conversely, for any choice of $\lambda > 0$, the Tikhonov solution:

$$f_{\lambda}^* = \arg\min_{f \in \mathcal{F}} L(f) + \lambda \Omega(f)$$

is also an Ivanov solution for some r > 0. That is, $\exists r > 0$ such that

$$f_{\lambda}^* = \underset{f \in \mathcal{F}}{\operatorname{arg\,min}} L(f) \text{ s.t. } \Omega(f) \leqslant r$$

 ℓ_{1} and ℓ_{2} Regularization

 ℓ_1 and ℓ_2 Regularization

Linear Least Squares Regression

Consider linear models

$$\mathcal{F} = \left\{ f : \mathbf{R}^d \to \mathbf{R} \mid f(x) = w^T x \text{ for } w \in \mathbf{R}^d \right\}$$

- Loss: $\ell(\hat{y}, y) = (y \hat{y})^2$
- Training data $\mathcal{D}_n = ((x_1, y_1), \dots, (x_n, y_n))$
- Linear least squares regression is ERM for ℓ over \mathcal{F} :

$$\hat{w} = \underset{w \in \mathbb{R}^d}{\arg\min} \frac{1}{n} \sum_{i=1}^n \left\{ w^T x_i - y_i \right\}^2$$

- Can **overfit** when *d* is large compared to *n*.
- e.g.: $d \gg n$ very common in Natural Language Processing problems (e.g. a 1M features for 10K documents).

Ridge Regression: Workhorse of Modern Data Science

Ridge Regression (Tikhonov Form)

The ridge regression solution for regularization parameter $\lambda\geqslant 0$ is

$$\hat{w} = \arg\min_{w \in \mathbf{R}^d} \frac{1}{n} \sum_{i=1}^n \left\{ w^T x_i - y_i \right\}^2 + \lambda ||w||_2^2,$$

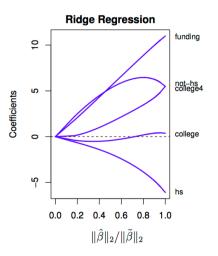

where $||w||_2^2 = w_1^2 + \cdots + w_d^2$ is the square of the ℓ_2 -norm.

Ridge Regression (Ivanov Form)

The ridge regression solution for complexity parameter $r \ge 0$ is

$$\hat{w} = \arg\min_{\|w\|_{2}^{2} \leq r} \frac{1}{n} \sum_{i=1}^{n} \left\{ w^{T} x_{i} - y_{i} \right\}^{2}.$$

Ridge Regression: Regularization Path

 $\tilde{\beta}$ is unregularized solution; $\hat{\beta}$ is the ridge solution.

Plot from Hastie, Tibshirani, and Wainwright's Statistical Learning with Sparsity, Figure 2.1

Lasso Regression: Workhorse (2) of Modern Data Science

Lasso Regression (Tikhonov Form)

The lasso regression solution for regularization parameter $\lambda \geqslant 0$ is

$$\hat{w} = \arg\min_{w \in \mathbf{R}^d} \frac{1}{n} \sum_{i=1}^n \left\{ w^T x_i - y_i \right\}^2 + \lambda ||w||_1,$$

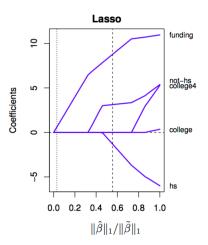

where $||w||_1 = |w_1| + \cdots + |w_d|$ is the ℓ_1 -norm.

Lasso Regression (Ivanov Form)

The lasso regression solution for complexity parameter $r \geqslant 0$ is

$$\hat{w} = \underset{\|w\|_{1} \leq r}{\arg\min} \frac{1}{n} \sum_{i=1}^{n} \{w^{T} x_{i} - y_{i}\}^{2}.$$

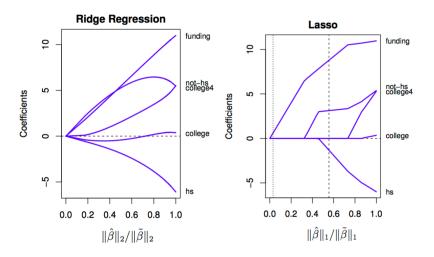

Lasso Regression: Regularization Path

 $\tilde{\beta}$ is unregularized solution; $\hat{\beta}$ is the lasso solution.

Plot from Hastie, Tibshirani, and Wainwright's Statistical Learning with Sparsity, Figure 2.1

Ridge vs. Lasso: Regularization Paths

Plot from Hastie, Tibshirani, and Wainwright's Statistical Learning with Sparsity, Figure 2.1

Lasso Gives Feature Sparsity: So What?

Coefficient are $0 \implies$ don't need those features. What's the gain?

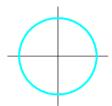

- Time/expense to compute/buy features
- Memory to store features (e.g. real-time deployment)
- Identifies the important features
- Better prediction? sometimes
- As a feature-selection step for training a slower non-linear model

Ivanov and Tikhonov Equivalent?

- For ridge regression and lasso regression,
 - the Ivanov and Tikhonov formulations are equivalent
 - [We may prove this in homework assignment 3.]
- We will use whichever form is most convenient.

The ℓ_1 and ℓ_2 Norm Constraints

- For visualization, restrict to 2-dimensional input space
- $\mathcal{F} = \{f(x) = w_1x_1 + w_2x_2\}$ (linear hypothesis space)
- Represent \mathcal{F} by $\{(w_1, w_2) \in \mathbb{R}^2\}$.
 - ℓ_2 contour: $w_1^2 + w_2^2 = r$

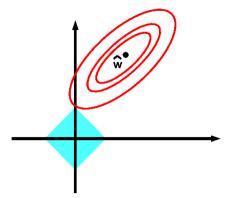

• ℓ_1 contour: $|w_1| + |w_2| = r$

Where are the "sparse" solutions?

The Famous Picture for ℓ_1 Regularization

• $f_r^* = \operatorname{arg\,min}_{w \in \mathbb{R}^2} \frac{1}{n} \sum_{i=1}^n (w^T x_i - y_i)^2$ subject to $|w_1| + |w_2| \leqslant r$

- Red lines: contours of $\hat{R}_n(w) = \sum_{i=1}^n (w^T x_i y_i)^2$.
- Blue region: Area satisfying complexity constraint: $|w_1| + |w_2| \le r$

KPM Fig. 13.3

The Empirical Risk for Square Loss

• Denote the empirical risk of $f(x) = w^T x$ by

$$\hat{R}_n(w) = \frac{1}{n} ||Xw - y||^2$$

- \hat{R}_n is minimized by $\hat{w} = (X^T X)^{-1} X^T y$, the OLS solution.
- What does \hat{R}_n look like around \hat{w} ?

The Empirical Risk for Square Loss

• By "completing the square", we can show for any $w \in \mathbb{R}^d$:

$$\hat{R}_{n}(w) = \frac{1}{n}(w - \hat{w})^{T}X^{T}X(w - \hat{w}) + \hat{R}_{n}(\hat{w})$$

• Set of w with $\hat{R}_n(w)$ exceeding $\hat{R}_n(\hat{w})$ by c>0 is

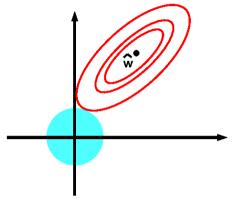

$$\left\{ w \mid \hat{R}_{n}(w) = c + \hat{R}_{n}(\hat{w}) \right\} = \left\{ w \mid (w - \hat{w})^{T} X^{T} X (w - \hat{w}) = c \right\},$$

which is an ellipsoid centered at \hat{w} .

• We'll derive this in homework #2.

The Famous Picture for ℓ_2 Regularization

• $f_r^* = \operatorname{arg\,min}_{w \in \mathbb{R}^2} \sum_{i=1}^n (w^T x_i - y_i)^2$ subject to $w_1^2 + w_2^2 \leqslant r$

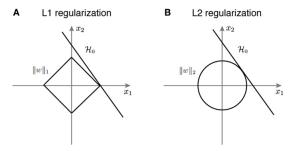

- Red lines: contours of $\hat{R}_n(w) = \sum_{i=1}^n (w^T x_i y_i)^2$.
- Blue region: Area satisfying complexity constraint: $w_1^2 + w_2^2 \leqslant r$

KPM Fig. 13.3

The Quora Picture

 From Quora: "Why is L1 regularization supposed to lead to sparsity than L2?"

- Doesn't seem like this figure represents the situation well...
- But maybe sometimes it does?

Finding the Lasso Solution

How to find the Lasso solution?

• How to solve the Lasso?

$$\min_{w \in \mathbf{R}^d} \sum_{i=1}^{n} (w^T x_i - y_i)^2 + \lambda ||w||_1$$

• $||w||_1$ is not differentiable!

Splitting a Number into Positive and Negative Parts

- Consider any number $a \in \mathbb{R}$.
- Let the **positive part** of a be

$$a^+ = a1(a \geqslant 0).$$

• Let the **negative part** of a be

$$a^{-} = -a1(a \leq 0).$$

- Do you see why $a^+ \geqslant 0$ and $a^- \geqslant 0$?
- How do you write a in terms of a^+ and a^- ?
- How do you write |a| in terms of a^+ and a^- ?

How to find the Lasso solution?

• The Lasso problem

$$\min_{w \in \mathbf{R}^d} \sum_{i=1}^n (w^T x_i - y_i)^2 + \lambda ||w||_1$$

- Replace each w_i by $w_i^+ w_i^-$.
- Write $w^+ = \left(w_1^+, \dots, w_d^+\right)$ and $w^- = \left(w_1^-, \dots, w_d^-\right)$.

The Lasso as a Quadratic Program

• Substituting $w = w^+ - w^-$ and $|w| = w^+ + w^-$, Lasso problem is:

$$\begin{aligned} & \min_{w^+, w^- \in \mathbf{R}^d} \sum_{i=1}^n \left(\left(w^+ - w^- \right)^T x_i - y_i \right)^2 + \lambda \mathbf{1}^T \left(w^+ + w^- \right) \\ & \text{subject to } w_i^+ \geqslant 0 \text{ for all } i \\ & w_i^- \geqslant 0 \text{ for all } i \end{aligned}$$

- Objective is differentiable (in fact, convex and quadratic)
- 2d variables vs d variables
- 2d constraints vs no constraints
- A "quadratic program": a convex quadratic objective with linear constraints.
 - Could plug this into a generic QP solver.

Projected SGD

$$\begin{aligned} & \min_{w^+, w^- \in \mathbf{R}^d} \sum_{i=1}^n \left(\left(w^+ - w^- \right)^T x_i - y_i \right)^2 + \lambda \mathbf{1}^T \left(w^+ + w^- \right) \\ & \text{subject to } w_i^+ \geqslant 0 \text{ for all } i \\ & w_i^- \geqslant 0 \text{ for all } i, \end{aligned}$$

where 1 represents a column vector of 1's in \mathbb{R}^d .

- Solution:
 - Take a stochastic gradient step
 - "Project" w^+ and w^- into the constraint set
 - In other words, any component of w^+ or w^- is negative, make it 0.

Coordinate Descent Method

- Goal: Minimize $L(w) = L(w_1, ..., w_d)$ over $w = (w_1, ..., w_d) \in \mathbb{R}^d$.
- In gradient descent or SGD,
 - \bullet each step potentially changes all entries of w.
- In each step of coordinate descent,
 - we adjust only a single w_i .
- In each step, solve

$$w_i^{\text{new}} = \underset{w_i}{\operatorname{arg\,min}} L(w_1, \dots, w_{i-1}, \mathbf{w_i}, w_{i+1}, \dots, w_d)$$

- Solving this argmin may itself be an iterative process.
- Coordinate descent is great when
 - it's easy or easier to minimize w.r.t. one coordinate at a time

Coordinate Descent Method

Coordinate Descent Method

Goal: Minimize $L(w) = L(w_1, \dots w_d)$ over $w = (w_1, \dots, w_d) \in \mathbb{R}^d$.

- Initialize $w^{(0)} = 0$
- while not converged:
 - Choose a coordinate $j \in \{1, ..., d\}$
 - $\bullet \ \ w_j^{\mathsf{new}} \leftarrow \arg\min_{w_j} L(w_1^{(t)}, \dots, w_{j-1}^{(t)}, \mathbf{w_j}, w_{j+1}^{(t)}, \dots, w_d^{(t)})$
 - $w^{(t+1)} \leftarrow w^{(t)}$
 - $w_i^{(t+1)} \leftarrow w_i^{\mathsf{new}}$
 - $t \leftarrow t+1$
- Random coordinate choice \implies stochastic coordinate descent
- Cyclic coordinate choice \implies cyclic coordinate descent

Coordinate Descent Method for Lasso

- Why mention coordinate descent for Lasso?
- In Lasso, the coordinate minimization has a closed form solution!

Coordinate Descent Method for Lasso

Closed Form Coordinate Minimization for Lasso

$$\hat{w}_{j} = \underset{w_{j} \in \mathbb{R}}{\arg \min} \sum_{i=1}^{n} (w^{T} x_{i} - y_{i})^{2} + \lambda |w|_{1}$$

Then

$$\hat{w}_{j}(c_{j}) = \begin{cases} (c_{j} + \lambda)/a_{j} & \text{if } c_{j} < -\lambda \\ 0 & \text{if } c_{j} \in [-\lambda, \lambda] \\ (c_{j} - \lambda)/a_{j} & \text{if } c_{j} > \lambda \end{cases}$$

$$a_j = 2\sum_{i=1}^n x_{i,j}^2$$
 $c_j = 2\sum_{i=1}^n x_{i,j}(y_i - w_{-j}^T x_{i,-j})$

where w_{-i} is w without component j and similarly for $x_{i,-i}$.

Coordinate Descent: When does it work?

- Suppose we're minimizing $f : \mathbb{R}^d \to \mathbb{R}$.
- Sufficient conditions:

 - 2 f is strictly convex in each coordinate
- But lasso objective

$$\sum_{i=1}^{n} (w^{T} x_{i} - y_{i})^{2} + \lambda ||w||_{1}$$

is not differentiable...

• Luckily there are weaker conditions...

Coordinate Descent: The Separability Condition

Theorem

^a If the objective f has the following structure

$$f(w_1,...,w_d) = g(w_1,...,g_d) + \sum_{j=1}^d h_j(x_j),$$

where

- $g: \mathbb{R}^d \to \mathbb{R}$ is differentiable and convex, and
- each $h_j : R \to R$ is convex (but not necessarily differentiable)

then the coordinate descent algorithm converges to the global minimum.

^aTseng 1988: "Coordinate ascent for maximizing nondifferentiable concave functions", Technical Report LIDS-P

Coordinate Descent Method – Variation

- Suppose there's no closed form? (e.g. logistic regression)
- Do we really need to fully solve each inner minimization problem?
- A single projected gradient step is enough for ℓ_1 regularization!
 - Shalev-Shwartz & Tewari's "Stochastic Methods..." (2011)

Stochastic Coordinate Descent for Lasso – Variation

• Let $\tilde{w} = (w^+, w^-) \in \mathbb{R}^{2d}$ and

$$L(\tilde{w}) = \sum_{i=1}^{n} ((w^{+} - w^{-})^{T} x_{i} - y_{i})^{2} + \lambda (w^{+} + w^{-})$$

Stochastic Coordinate Descent for Lasso - Variation

Goal: Minimize $L(\tilde{w})$ s.t. $w_i^+, w_i^- \ge 0$ for all i.

- Initialize $\tilde{w}^{(0)} = 0$
 - while not converged:
 - Randomly choose a coordinate $j \in \{1, ..., 2d\}$
 - $\tilde{w}_i \leftarrow \tilde{w}_i + \max\{-\tilde{w}_i, -\nabla_i L(\tilde{w})\}$
