Gaussian Mixture Models

Probabilistic Model for Clustering

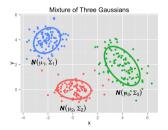

- Let's consider a generative model for the data.
- Suppose
 - There are k clusters.
 - 2 We have a probability density for each cluster.
- Generate a point as follows
 - Choose a random cluster $z \in \{1, 2, ..., k\}$.
 - **2** Choose a point from the distribution for cluster z.

Gaussian Mixture Model (k = 3)

Gaussian Mixture Model Parameters (k Components)

For now, **suppose all these parameters are known**. We'll discuss how to **learn** or **estimate** them later.

David S. Rosenberg (Bloomberg ML EDU)

Gaussian Mixture Model: Joint Distribution

• Factorize the joint density:

$$p(x,z) = p(z)p(x \mid z)$$

= $\pi_z \mathcal{N}(x \mid \mu_z, \Sigma_z)$

- π_z is probability of choosing cluster *z*.
 - $x \mid z$ has distribution $\mathcal{N}(\mu_z, \Sigma_z)$.
 - *z* corresponding to *x* is the true cluster assignment.
- Suppose we know the model parameters π_z, μ_z, Σ_z .
- Then we can easily evaluate the joint density p(x, z).

- We observe *x*.
- We don't observe z (the cluster assignment).
- Cluster assignment z is called a hidden variable or latent variable.

Definition

A latent variable model is a probability model for which certain variables are never observed.

e.g. The Gaussian mixture model is a latent variable model.

The GMM "Inference" Problem

- We observe x. We want to know its cluster assignment z.
- The conditional probability for cluster z given x is

 $p(z \mid x) = p(x, z) / p(x)$

- The conditional distribution is a **soft assignment** to clusters.
- A hard assignment is

$$z^* = \underset{z \in \{1, \dots, k\}}{\operatorname{arg\,max}} p(z \mid x).$$

• So if we have the model, clustering is trival.

Mixture Models

Gaussian Mixture Model: Marginal Distribution

• The marginal distribution for a single observation x is

$$p(x) = \sum_{z=1}^{k} p(x, z)$$
$$= \sum_{z=1}^{k} \pi_z \mathcal{N}(x \mid \mu_z, \Sigma_z)$$

- Note that p(x) is a convex combination of probability densities.
- This is a common form for a probability model...

Mixture Distributions (or Mixture Models)

Definition

A probability density p(x) represents a **mixture distribution** or **mixture model**, if we can write it as a **convex combination** of probability densities. That is,

$$p(x) = \sum_{i=1}^{k} w_i p_i(x),$$

where $w_i \ge 0$, $\sum_{i=1}^{k} w_i = 1$, and each p_i is a probability density.

- In our Gaussian mixture model, x has a mixture distribution.
- More constructively, let S be a set of probability distributions:
 - Choose a distribution randomly from *S*.
 - **2** Sample *x* from the chosen distribution.
- Then x has a mixture distribution.

Learning in Gaussian Mixture Models

The GMM "Learning" Problem

- Given data x_1, \ldots, x_n drawn from a GMM,
- Estimate the parameters:

 $\begin{array}{ll} \mbox{Cluster probabilities}: & \pi = (\pi_1, \ldots, \pi_k) \\ & \mbox{Cluster means}: & \mu = (\mu_1, \ldots, \mu_k) \\ \mbox{Cluster covariance matrices:} & \Sigma = (\Sigma_1, \ldots \Sigma_k) \end{array}$

- Once we have the parameters, we're done.
- Just do "inference" to get cluster assignments.

Estimating/Learning the Gaussian Mixture Model

- One approach to learning is maximum likelihood
 - find parameter values with highest likelihood for the observed data.
- The model likelihood for $\mathcal{D} = (x_1, \dots, x_n)$ sampled iid from a GMM is

$$L(\pi, \mu, \Sigma) = \prod_{i=1}^{n} p(x_i)$$
$$= \prod_{i=1}^{n} \sum_{z=1}^{k} \pi_z \mathcal{N}(x_i \mid \mu_z, \Sigma_z).$$

• As usual, we'll take our objective function to be the log of this:

$$J(\pi, \mu, \Sigma) = \sum_{i=1}^{n} \log \left\{ \sum_{z=1}^{k} \pi_z \mathcal{N}(x_i \mid \mu_z, \Sigma_z) \right\}$$

Review: Estimating a Gaussian Distribution

• Recall that the density for $x \sim \mathcal{N}(\mu, \Sigma)$ is

$$p(x \mid \mu, \Sigma) = \frac{1}{\sqrt{|2\pi\Sigma|}} \exp\left(-\frac{1}{2}(x-\mu)^{T}\Sigma^{-1}(x-\mu)\right)$$

• And the log-density is

$$\log p(x \mid \mu, \Sigma) = -\frac{1}{2} \log |2\pi\Sigma| - \frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu)$$

To estimate μ and Σ from a sample x₁,..., x_n i.i.d. N(μ, Σ), we'll maximize the log joint density:

$$\sum_{i=1}^{n} \log p(x_i \mid \mu, \Sigma) = -\frac{n}{2} \log |2\pi\Sigma| - \frac{1}{2} \sum_{i=1}^{n} (x_i - \mu)^T \Sigma^{-1} (x_i - \mu)$$

Review: Estimating a Gaussian Distribution

To estimate μ and Σ from a sample x₁,..., x_n i.i.d. N(μ, Σ), we'll maximize the log joint density:

$$J(\mu, \Sigma) = \sum_{i=1}^{n} \log p(x \mid \mu, \Sigma) = -\frac{n}{2} \log |2\pi\Sigma| - \frac{1}{2} \sum_{i=1}^{n} (x_i - \mu)^T \Sigma^{-1} (x_i - \mu)$$

 \bullet This is a solid exercise in vector and matrix differentiation. Find $\hat{\mu}$ and $\hat{\Sigma}$ satisfying

$$\nabla_{\mu}J(\mu,\Sigma)=0 \qquad \nabla_{\Sigma}J(\mu,\Sigma)=0$$

• We get a closed form solution:

$$\hat{\mu}_{\mathsf{MLE}} = \frac{1}{n} \sum_{i=1}^{n} x_i$$

$$\hat{\Sigma}_{\mathsf{MLE}} = \frac{1}{n} \sum_{i=1}^{n} (x_i - \hat{\mu}_{\mathsf{MLE}})^T (x_i - \hat{\mu}_{\mathsf{MLE}})$$

Properties of the GMM Log-Likelihood

• GMM log-likelihood:

$$J(\pi,\mu,\Sigma) = \sum_{i=1}^{n} \log \left\{ \sum_{z=1}^{k} \frac{\pi_z}{\sqrt{|2\pi\Sigma_z|}} \exp\left(-\frac{1}{2}(x-\mu_z)^T \Sigma^{-1}(x-\mu_z)\right) \right\}$$

• Let's compare to the log-likelihood for a single Gaussian:

$$J(\mu, \Sigma) = -\frac{n}{2} \log |2\pi\Sigma| - \frac{1}{2} \sum_{i=1}^{n} (x_i - \mu)^T \Sigma^{-1}(x_i - \mu)$$

- For a single Gaussian, the log cancels the exp in the Gaussian density.
 - \implies Things simplify a lot.
- For the GMM, the sum inside the log prevents this cancellation.
 - $\bullet \implies$ Expression more complicated. No closed form expression for MLE.

Issues with MLE for GMM

Identifiability Issues for GMM

• Suppose we have found parameters

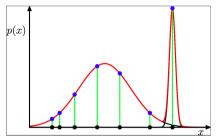

Cluster probabilities :	$\pi = (\pi_1, \ldots, \pi_k)$
Cluster means :	$\boldsymbol{\mu} = (\mu_1, \ldots, \mu_k)$
Cluster covariance matrices:	$\Sigma = (\Sigma_1, \dots \Sigma_k)$

that are at a local minimum.

- What happens if we shuffle the clusters? e.g. Switch the labels for clusters 1 and 2.
- We'll get the same likelihood. How many such equivalent settings are there?
- Assuming all clusters are distinct, there are k! equivalent solutions.
- Not a problem *per se*, b ut something to be aware of.

Singularities for GMM

• Consider the following GMM for 7 data points:

- Let σ^2 be the variance of the skinny component.
- What happens to the likelihood as $\sigma^2 \to 0?$
- In practice, we end up in local minima that do not have this problem.
 - Or keep restarting optimization until we do.
- Bayesian approach or regularization will also solve the problem.

From Bishop's Pattern recognition and machine learning, Figure 9.7.

David S. Rosenberg (Bloomberg ML EDU)

Gradient Descent / SGD for GMM

• What about running gradient descent or SGD on

$$J(\pi, \mu, \Sigma) = -\sum_{i=1}^{n} \log \left\{ \sum_{z=1}^{k} \pi_z \mathcal{N}(x_i \mid \mu_z, \Sigma_z) \right\}?$$

- Can be done, in principle but need to be clever about it.
- Each matrix $\Sigma_1, \ldots, \Sigma_k$ has to be positive semidefinite.
- How to maintain that constraint?
 - Rewrite $\Sigma_i = M_i M_i^T$, where M_i is an unconstrained matrix.
 - Then Σ_i is positive semidefinite.
- Even then, pure gradient-based methods have trouble.¹

David S. Rosenberg (Bloomberg ML EDU)

¹See Hosseini and Sra's Manifold Optimization for Gaussian Mixture Models for discussion and further references.

The EM Algorithm for GMM

MLE for Gaussian Model

- Let's start by considering the MLE for the Gaussian model.
- For data $\mathcal{D} = \{x_1, \dots, x_n\}$, the log likelihood is given by

$$\sum_{i=1}^{n} \log \mathcal{N}(x_i \mid \mu, \Sigma) = -\frac{nd}{2} \log (2\pi) - \frac{n}{2} \log |\Sigma| - \frac{1}{2} \sum_{i=1}^{n} (x_i - \mu)' \Sigma^{-1}(x_i - \mu).$$

• With some calculus, we find that the MLE parameters are

$$\mu_{\text{MLE}} = \frac{1}{n} \sum_{i=1}^{n} x_i$$

$$\Sigma_{\text{MLE}} = \frac{1}{n} \sum_{i=1}^{n} (x_i - \mu_{\text{MLE}}) (x_i - \mu_{\text{MLE}})^T$$

- For GMM, If we knew the cluster assignment z_i for each x_i ,
 - we could compute the MLEs for each cluster.

Estimating a Fully-Observed GMM

- Suppose we observe $(x_1, z_1), \ldots, (x_n, z_n)$ i.i.d. from GMM p(x, z).
- Them find MLE is easy:

$$n_{z} = \sum_{i=1}^{n} 1(z_{i} = z)$$

$$\hat{\pi}(z) = \frac{n_{z}}{n}$$

$$\hat{\mu}_{z} = \frac{1}{n_{z}} \sum_{i:z_{i} = z} x_{i}$$

$$\hat{\Sigma}_{z} = \frac{1}{n_{z}} \sum_{i:z_{i} = z} (x_{i} - \hat{\mu}_{z}) (x_{i} - \hat{\mu}_{z})^{T}.$$

• In the EM algorithm we will modify the equations to handle our evolving soft assignments, which we will call responsibilities.

Cluster Responsibilities: Some New Notation

• Denote the probability that observed value x_i comes from cluster j by

$$\gamma_i^j = p(z=j \mid x=x_i).$$

- The **responsibility** that cluster j takes for observation x_i .
- Computationally,

$$\begin{aligned} \gamma_{i}^{j} &= p(z = j \mid x_{i}) \,. \\ &= p(z = j, x_{i}) / p(x_{i}) \\ &= \frac{\pi_{j} \mathcal{N}(x_{i} \mid \mu_{j}, \Sigma_{j})}{\sum_{c=1}^{k} \pi_{c} \mathcal{N}(x_{i} \mid \mu_{c}, \Sigma_{c})} \end{aligned}$$

- The vector $(\gamma_i^1, \dots, \gamma_i^k)$ is exactly the **soft assignment** for x_i .
- Let $n_c = \sum_{i=1}^n \gamma_i^c$ be the "number" of points "soft assigned" to cluster c.

• If we know μ_j, Σ_j, π_j for all clusters j, then easy to find

$$\gamma_i^j = p(z = j \mid x_i)$$

- If we know the (soft) assignments, we can easily find estimates for π, Σ, μ .
- Repeatedly alternate these two steps.

EM Algorithm for GMM: Overview

• Initialize parameters μ , Σ , π .

(2) "E step". Evaluate the responsibilities using current parameters:

$$\gamma_i^j = \frac{\pi_j \mathcal{N}(x_i \mid \mu_j, \Sigma_j)}{\sum_{c=1}^k \pi_c \mathcal{N}(x_i \mid \mu_c, \Sigma_c)}$$

for $i = 1, \ldots, n$ and $j = 1, \ldots, k$.

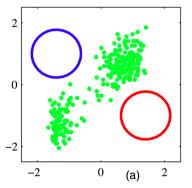

Image: "M step". Re-estimate the parameters using responsibilities:

$$\begin{split} \mu_c^{\text{new}} &= \frac{1}{n_c} \sum_{i=1}^n \gamma_i^c x_i \\ \Sigma_c^{\text{new}} &= \frac{1}{n_c} \sum_{i=1}^n \gamma_i^c (x_i - \mu_c^{\text{new}}) (x_i - \mu_c^{\text{new}})^T \\ \pi_c^{\text{new}} &= \frac{n_c}{n}, \end{split}$$

G Repeat from Step 2, until log-likelihood converges.

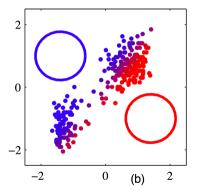

David S. Rosenberg (Bloomberg ML EDU)

• Initialization

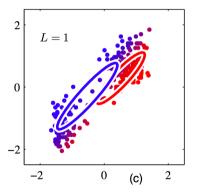

From Bishop's Pattern recognition and machine learning, Figure 9.8.

• First soft assignment:

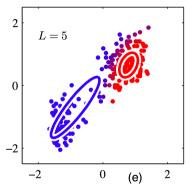

From Bishop's Pattern recognition and machine learning, Figure 9.8.

• First soft assignment:

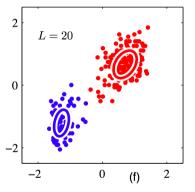

From Bishop's Pattern recognition and machine learning, Figure 9.8.

• After 5 rounds of EM:

From Bishop's Pattern recognition and machine learning, Figure 9.8.

• After 20 rounds of EM:

From Bishop's Pattern recognition and machine learning, Figure 9.8.

- EM for GMM seems a little like k-means.
- In fact, there is a precise correspondence.
- First, fix each cluster covariance matrix to be $\sigma^2 I$.
- As we take $\sigma^2 \rightarrow 0$, the update equations converge to doing *k*-means.
- If you do a quick experiment yourself, you'll find
 - Soft assignments converge to hard assignments.
 - Has to do with the tail behavior (exponential decay) of Gaussian.
