EM Algorithm for Latent Variable Models

## General Latent Variable Model

- Two sets of random variables: $z$ and $x$.
- $z$ consists of unobserved hidden variables.
- x consists of observed variables.
- Joint probability model parameterized by $\theta \in \Theta$ :

$$
p(x, z \mid \theta)
$$

## Definition

A latent variable model is a probability model for which certain variables are never observed.
e.g. The Gaussian mixture model is a latent variable model.

## Complete and Incomplete Data

- Suppose we have a data set $\mathcal{D}=\left(x_{1}, \ldots, x_{n}\right)$.
- To simplify notation, take $x$ to represent the entire dataset

$$
x=\left(x_{1}, \ldots, x_{n}\right),
$$

and $z$ to represent the corresponding unobserved variables

$$
z=\left(z_{1}, \ldots, z_{n}\right)
$$

- An observation of $x$ is called an incomplete data set.
- An observation $(x, z)$ is called a complete data set.

## Our Objectives

- Learning problem: Given incomplete dataset $\mathcal{D}=x=\left(x_{1}, \ldots, x_{n}\right)$, find MLE

$$
\hat{\theta}=\underset{\theta}{\arg \max } p(\mathcal{D} \mid \theta) .
$$

- Inference problem: Given $x$, find conditional distribution over $z$ :

$$
p\left(z_{i} \mid x_{i}, \theta\right) .
$$

- For Gaussian mixture model, learning is hard, inference is easy.
- For more complicated models, inference can also be hard. (See DSGA-1005)

## Log-Likelihood and Terminology

- Note that

$$
\underset{\theta}{\arg \max } p(x \mid \theta)=\underset{\theta}{\arg \max }[\log p(x \mid \theta)] .
$$

- Often easier to work with this "log-likelihood".
- We often call $p(x)$ the marginal likelihood,
- because it is $p(x, z)$ with $z$ "marginalized out":

$$
p(x)=\sum_{z} p(x, z)
$$

- We often call $p(x, y)$ the joint. (for "joint distribution")
- Similarly, $\log p(x)$ is the marginal log-likelihood.

## The EM Algorithm Key Idea

- Marginal log-likelihood is hard to optimize:

$$
\max _{\theta} \log p(x \mid \theta)
$$

- Typically the complete data log-likelihood is easy to optimize:

$$
\max _{\theta} \log p(x, z \mid \theta)
$$

- What if we had a distribution $q(z)$ for the latent variables $z$ ?
- Then maximize the expected complete data log-likelihood:

$$
\max _{\theta} \sum_{z} q(z) \log p(x, z \mid \theta)
$$

- EM assumes this maximization is relatively easy.

## Lower Bound for Marginal Log-Likelihood

- Let $q(z)$ be any PMF on $z$, the support of $z$ :

$$
\begin{aligned}
\log p(x \mid \theta) & =\log \left[\sum_{z} p(x, z \mid \theta)\right] \\
& =\log \left[\sum_{z} q(z)\left(\frac{p(x, z \mid \theta)}{q(z)}\right)\right] \quad \text { (log of an expectation) } \\
& \geqslant \sum_{z} q(z) \log \left(\frac{p(x, z \mid \theta)}{q(z)}\right) \quad \text { (expectation of } \log \text { ) }
\end{aligned}
$$

- Inequality is by Jensen's, by concavity of the log.

This inequality is the basis for "variational methods", of which EM is a basic example.

## The ELBO

- For any PMF $q(z)$, we have a lower bound on the marginal log-likelihood

$$
\log p(x \mid \theta) \geqslant \underbrace{\sum_{z} q(z) \log \left(\frac{p(x, z \mid \theta)}{q(z)}\right)}_{\mathcal{L}(q, \theta)}
$$

- Marginal $\log$ likelihood $\log p(x \mid \theta)$ also called the evidence.
- $\mathcal{L}(q, \theta)$ is the evidence lower bound, or "ELBO".

In EM algorithm (and variational methods more generally), we maximize $\mathcal{L}(q, \theta)$ over $q$ and $\theta$.

## MLE, EM, and the ELBO

- For any PMF $q(z)$, we have a lower bound on the marginal log-likelihood

$$
\log p(x \mid \theta) \geqslant \mathcal{L}(q, \theta) .
$$

- The MLE is defined as a maximum over $\theta$ :

$$
\hat{\theta}_{\mathrm{MLE}}=\underset{\theta}{\arg \max } \log p(x \mid \theta) .
$$

- In EM algorithm, we maximize the lower bound (ELBO) over $\theta$ and $q$ :

$$
\hat{\theta}_{\mathrm{EM}}=\underset{\theta}{\arg \max }\left[\max _{q} \mathcal{L}(q, \theta)\right]
$$

## A Family of Lower Bounds

- For each $q$, we get a lower bound function: $\log p(x \mid \theta) \geqslant \mathcal{L}(q, \theta) \forall \theta$.
- Two lower bounds (blue and green curves), as functions of $\theta$ :

- Ideally, we'd find the maximum of the red curve. Maximum of green is close.

From Bishop's Pattern recognition and machine learning, Figure 9.14.

## EM: Coordinate Ascent on Lower Bound

- Choose sequence of q's and $\theta$ 's by "coordinate ascent".
- EM Algorithm (high level):
(1) Choose initial $\theta^{\text {old }}$.
(2) Let $q^{*}=\arg \max _{q} \mathcal{L}\left(q, \theta^{\text {old }}\right)$
(3) Let $\theta^{\text {new }}=\arg \max _{\theta} \mathcal{L}\left(q^{*}, \theta^{\text {old }}\right)$.
(c) Go to step 2 , until converged.
- Will show: $p\left(x \mid \theta^{\text {new }}\right) \geqslant p\left(x \mid \theta^{\text {old }}\right)$
- Get sequence of $\theta$ 's with monotonically increasing likelihood.

## EM: Coordinate Ascent on Lower Bound

(1) Start at $\theta^{\text {old }}$.
(2) Find $q$ giving best lower bound at $\theta^{\text {old }} \Longrightarrow \mathcal{L}(q, \theta)$.
(0) $\theta^{\text {new }}=\arg ^{\max }{ }_{\theta} \mathcal{L}(q, \theta)$.

From Bishop's Pattern recognition and machine learning, Figure 9.14.

## EM: Next Steps

- We now give 2 different re-expressions of $\mathcal{L}(q, \theta)$ that make it easy to compute
- $\arg \max _{q} \mathcal{L}(q, \theta)$, for a given $\theta$, and
- $\arg \max _{\theta} \mathcal{L}(q, \theta)$, for a given $q$.

## ELBO in Terms of KL Divergence and Entropy

- Let's investigate the lower bound:

$$
\begin{aligned}
\mathcal{L}(q, \theta) & =\sum_{z} q(z) \log \left(\frac{p(x, z \mid \theta)}{q(z)}\right) \\
& =\sum_{z} q(z) \log \left(\frac{p(z \mid x, \theta) p(x \mid \theta)}{q(z)}\right) \\
& =\sum_{z} q(z) \log \left(\frac{p(z \mid x, \theta)}{q(z)}\right)+\sum_{z} q(z) \log p(x \mid \theta) \\
& =-\operatorname{KL}[q(z), p(z \mid x, \theta)]+\log p(x \mid \theta)
\end{aligned}
$$

- Amazing! We get back an equality for the marginal likelihood:

$$
\log p(x \mid \theta)=\mathcal{L}(q, \theta)+\operatorname{KL}[q(z), p(z \mid x, \theta)]
$$

## Maxizing over $q$ for fixed $\theta=\theta^{\text {old }}$

- Find q maximizing

$$
\mathcal{L}\left(q, \theta^{\text {old }}\right)=-\operatorname{KL}\left[q(z), p\left(z \mid x, \theta^{\text {old }}\right)\right]+\underbrace{\log p\left(x \mid \theta^{\text {old }}\right)}_{\text {no } q \text { here }}
$$

- Recall $\operatorname{KL}(p \| q) \geqslant 0$, and $\operatorname{KL}(p \| p)=0$.
- Best $q$ is $q^{*}(z)=p\left(z \mid x, \theta^{\text {old }}\right)$ and

$$
\mathcal{L}\left(q^{*}, \theta^{\text {old }}\right)=-\underbrace{\operatorname{KL}\left[p\left(z \mid x, \theta^{\text {old }}\right), p\left(z \mid x, \theta^{\text {old }}\right)\right]}_{=0}+\log p\left(x \mid \theta^{\text {old }}\right)
$$

- Summary:

$$
\begin{aligned}
\log p\left(x \mid \theta^{\text {old }}\right) & =\mathcal{L}\left(q^{*}, \theta^{\text {old }}\right) \quad\left(\text { tangent at } \theta^{\text {old }}\right) . \\
\log p(x \mid \theta) & \geqslant \mathcal{L}\left(q^{*}, \theta\right) \quad \forall \theta
\end{aligned}
$$

## Tight lower bound for any chosen $\theta$

For $\theta^{\text {old }}$, take $q(z)=p\left(z \mid x, \theta^{\text {old }}\right)$. Then
(1) $\log p(x \mid \theta) \geqslant \mathcal{L}(q, \theta) \forall \theta$. [Global lower bound].
(2) $\log p\left(x \mid \theta^{\text {old }}\right)=\mathcal{L}\left(q, \theta^{\text {old }}\right)$. [Lower bound is tight at $\theta^{\text {old }}$.]

From Bishop's Pattern recognition and machine learning, Figure 9.14.

## Maximizing over $\theta$ for fixed $q$

- Consider maximizing the lower bound $\mathcal{L}(q, \theta)$ :

$$
\begin{aligned}
\mathcal{L}(q, \theta) & =\sum_{z} q(z) \log \left(\frac{p(x, z \mid \theta)}{q(z)}\right) \\
& =\underbrace{\sum_{z} q(z) \log p(x, z \mid \theta)}_{\mathbb{E} \text { [complete data log-likelihood] }}-\underbrace{\sum_{z} q(z) \log q(z)}_{\text {no } \theta \text { here }}
\end{aligned}
$$

- Maximizing $\mathcal{L}(q, \theta)$ equivalent to maximizing $\mathbb{E}$ [complete data log-likelihood] (for fixed $q$ ).

## General EM Algorithm

(1) Choose initial $\theta^{\text {old }}$.
(3) Expectation Step

- Let $q^{*}(z)=p\left(z \mid x, \theta^{\text {old }}\right)$. [ $q^{*}$ gives best lower bound at $\theta^{\text {old }}$ ]
- Let

$$
J(\theta):=\mathcal{L}\left(q^{*}, \theta\right)=\underbrace{\sum_{z} q^{*}(z) \log \left(\frac{p(x, z \mid \theta)}{q^{*}(z)}\right)}_{\text {expectation w.r.t. } z \sim q^{*}(z)}
$$

(3) Maximization Step

$$
\theta^{\text {new }}=\underset{\theta}{\arg \max } J(\theta) .
$$

[Equivalent to maximizing expected complete log-likelihood.]
(9) Go to step 2, until converged.

## Does EM Work?

## EM Gives Monotonically Increasing Likelihood: By Picture

From Bishop's Pattern recognition and machine learning, Figure 9.14.

## EM Gives Monotonically Increasing Likelihood: By Math

(1) Start at $\theta^{\text {old }}$.
(2) Choose $q^{*}(z)=\arg \max _{q} \mathcal{L}\left(q, \theta^{\text {old }}\right)$. We've shown

$$
\log p\left(x \mid \theta^{\text {old }}\right)=\mathcal{L}\left(q^{*}, \theta^{\text {old }}\right)
$$

(3) Choose $\theta^{\text {new }}=\arg \max _{\theta} \mathcal{L}\left(q^{*}, \theta\right)$. So

$$
\mathcal{L}\left(q^{*}, \theta^{\text {new }}\right) \geqslant \mathcal{L}\left(q^{*}, \theta^{\text {old }}\right)
$$

Putting it together, we get

$$
\begin{array}{rlr}
\log p\left(x \mid \theta^{\text {new }}\right) & \geqslant \mathcal{L}\left(q^{*}, \theta^{\text {new }}\right) & \mathcal{L} \text { is a lower bound } \\
& \geqslant \mathcal{L}\left(q^{*}, \theta^{\text {old }}\right) & \text { By definition of } \theta^{\text {new }} \\
& =\log p\left(x \mid \theta^{\text {old }}\right) & \text { Bound is tight at } \theta^{\text {old }} .
\end{array}
$$

## Suppose We Maximize the ELBO.

- Suppose we have found a global maximum of $\mathcal{L}(q, \theta)$ :

$$
\mathcal{L}\left(q^{*}, \theta^{*}\right) \geqslant \mathcal{L}(q, \theta) \forall q, \theta,
$$

where of course

$$
q^{*}(z)=p\left(z \mid x, \theta^{*}\right)
$$

- Claim: $\theta^{*}$ is a global maximum of $\log p\left(x \mid \theta^{*}\right)$.
- Proof: For any $\theta^{\prime}$, we showed that for $q^{\prime}(z)=p\left(z \mid x, \theta^{\prime}\right)$ we have

$$
\begin{aligned}
\log p\left(x \mid \theta^{\prime}\right) & =\mathcal{L}\left(q^{\prime}, \theta^{\prime}\right)+\operatorname{KL}\left[q^{\prime}, p\left(z \mid x, \theta^{\prime}\right)\right] \\
& =\mathcal{L}\left(q^{\prime}, \theta^{\prime}\right) \\
& \leqslant \mathcal{L}\left(q^{*}, \theta^{*}\right) \\
& =\log p\left(x \mid \theta^{*}\right)
\end{aligned}
$$

## Convergence of EM

- Let $\theta_{n}$ be value of EM algorithm after $n$ steps.
- Define "transition function" $M(\cdot)$ such that $\theta_{n+1}=M\left(\theta_{n}\right)$.
- Suppose log-likelihood function $\ell(\theta)=\log p(x \mid \theta)$ is differentiable.
- Let $S$ be the set of stationary points of $\ell(\theta)$. (i.e. $\nabla_{\theta} \ell(\theta)=0$ )

## Theorem

Under mild regularity conditions ${ }^{a}$, for any starting point $\theta_{0}$,

- $\lim _{n \rightarrow \infty} \theta_{n}=\theta^{*}$ for some stationary point $\theta^{*} \in S$ and
- $\theta^{*}$ is a fixed point of the $E M$ algorithm, i.e. $M\left(\theta^{*}\right)=\theta^{*}$. Moreover,
- $\ell\left(\theta_{n}\right)$ strictly increases to $\ell\left(\theta^{*}\right)$ as $n \rightarrow \infty$, unless $\theta_{n} \equiv \theta^{*}$.

[^0]
## Variations on EM

## EM Gives Us Two New Problems

- The "E" Step: Computing

$$
J(\theta):=\mathcal{L}\left(q^{*}, \theta\right)=\sum_{z} q^{*}(z) \log \left(\frac{p(x, z \mid \theta)}{q^{*}(z)}\right)
$$

- The " $M$ " Step: Computing

$$
\theta^{\text {new }}=\underset{\theta}{\arg \max } J(\theta) .
$$

- Either of these can be too hard to do in practice.

## Generalized EM (GEM)

- Addresses the problem of a difficult "M" step.
- Rather than finding

$$
\theta^{\text {new }}=\underset{\theta}{\arg \max } J(\theta),
$$

find any $\theta^{\text {new }}$ for which

$$
J\left(\theta^{\text {new }}\right)>J\left(\theta^{\text {old }}\right)
$$

- Can use a standard nonlinear optimization strategy
- e.g. take a gradient step on J.
- We still get monotonically increasing likelihood.

## EM and More General Variational Methods

- Suppose "E" step is difficult:
- Hard to take expectation w.r.t. $q^{*}(z)=p\left(z \mid x, \theta^{\text {old }}\right)$.
- Solution: Restrict to distributions $Q$ that are easy to work with.
- Lower bound now looser:

$$
q^{*}=\underset{q \in \mathcal{Q}}{\arg \min } \operatorname{KL}\left[q(z), p\left(z \mid x, \theta^{\text {old }}\right)\right]
$$

## EM in Bayesian Setting

- Suppose we have a prior $p(\theta)$.
- Want to find MAP estimate: $\hat{\theta}_{\text {MAP }}=\arg \max _{\theta} p(\theta \mid x)$ :

$$
\begin{aligned}
p(\theta \mid x) & =p(x \mid \theta) p(\theta) / p(x) \\
\log p(\theta \mid x) & =\log p(x \mid \theta)+\log p(\theta)-\log p(x)
\end{aligned}
$$

- Still can use our lower bound on $\log p(x, \theta)$.

$$
J(\theta):=\mathcal{L}\left(q^{*}, \theta\right)=\sum_{z} q^{*}(z) \log \left(\frac{p(x, z \mid \theta)}{q^{*}(z)}\right)
$$

- Maximization step becomes

$$
\theta^{\text {new }}=\underset{\theta}{\arg \max }[J(\theta)+\log p(\theta)]
$$

- Homework: Convince yourself our lower bound is still tight at $\theta$.

## Summer Homework: Gaussian Mixture Model (Hints)

## Homework: Derive EM for GMM from General EM Algorithm

- Subsequent slides may help set things up.
- Key skills:
- MLE for multivariate Gaussian distributions.
- Lagrange multipliers

## Gaussian Mixture Model (k Components)

- GMM Parameters

$$
\begin{aligned}
\text { Cluster probabilities: } & \pi=\left(\pi_{1}, \ldots, \pi_{k}\right) \\
\text { Cluster means: } & \mu=\left(\mu_{1}, \ldots, \mu_{k}\right) \\
\text { Cluster covariance matrices: } & \Sigma=\left(\Sigma_{1}, \ldots \Sigma_{k}\right)
\end{aligned}
$$

- Let $\theta=(\pi, \mu, \Sigma)$.
- Marginal log-likelihood

$$
\log p(x \mid \theta)=\log \left\{\sum_{z=1}^{k} \pi_{z} \mathcal{N}\left(x \mid \mu_{z}, \Sigma_{z}\right)\right\}
$$

## $q^{*}(z)$ are "Soft Assignments"

- Suppose we observe $n$ points: $X=\left(x_{1}, \ldots, x_{n}\right) \in \mathrm{R}^{n \times d}$.
- Let $z_{1}, \ldots, z_{n} \in\{1, \ldots, k\}$ be corresponding hidden variables.
- Optimal distribution $q^{*}$ is:

$$
q^{*}(z)=p(z \mid x, \theta) .
$$

- Convenient to define the conditional distribution for $z_{i}$ given $x_{i}$ as

$$
\begin{aligned}
\gamma_{i}^{j} & :=p\left(z=j \mid x_{i}\right) \\
& =\frac{\pi_{j} \mathcal{N}\left(x_{i} \mid \mu_{j}, \Sigma_{j}\right)}{\sum_{c=1}^{k} \pi_{c} \mathcal{N}\left(x_{i} \mid \mu_{c}, \Sigma_{c}\right)}
\end{aligned}
$$

## Expectation Step

- The complete log-likelihood is

$$
\begin{aligned}
\log p(x, z \mid \theta) & =\sum_{i=1}^{n} \log \left[\pi_{z} \mathcal{N}\left(x_{i} \mid \mu_{z}, \Sigma_{z}\right)\right] \\
& =\sum_{i=1}^{n}(\log \pi_{z}+\underbrace{\log \mathcal{N}\left(x_{i} \mid \mu_{z}, \Sigma_{z}\right)}_{\text {simplifies nicely }})
\end{aligned}
$$

- Take the expected complete log-likelihood w.r.t. $q^{*}$ :

$$
\begin{aligned}
J(\theta) & =\sum_{z} q^{*}(z) \log p(x, z \mid \theta) \\
& =\sum_{i=1}^{n} \sum_{j=1}^{k} \gamma_{i}^{j}\left[\log \pi_{j}+\log \mathcal{N}\left(x_{i} \mid \mu_{j}, \Sigma_{j}\right)\right]
\end{aligned}
$$

## Maximization Step

- Find $\theta^{*}$ maximizing $J(\theta)$ :

$$
\begin{aligned}
\mu_{c}^{\text {new }} & =\frac{1}{n_{c}} \sum_{i=1}^{n} \gamma_{i}^{c} x_{i} \\
\Sigma_{c}^{\text {new }} & =\frac{1}{n_{c}} \sum_{i=1}^{n} \gamma_{i}^{c}\left(x_{i}-\mu_{\mathrm{MLE}}\right)\left(x_{i}-\mu_{\mathrm{MLE}}\right)^{T} \\
\pi_{c}^{\text {new }} & =\frac{n_{c}}{n}
\end{aligned}
$$

for each $c=1, \ldots, k$.

[^0]:    ${ }^{a}$ For details, see "Parameter Convergence for EM and MM Algorithms" by Florin Vaida in Statistica Sinica (2005). http://www3.stat.sinica.edu.tw/statistica/oldpdf/a15n316.pdf
